ASSIGNMENT-1

- Software process model

The waterfall model is a linear sequential process where software development progresses through fixed phases

Requirements → Design → Coding & unit testing → Integration → Operation & maintenance

Advantages:

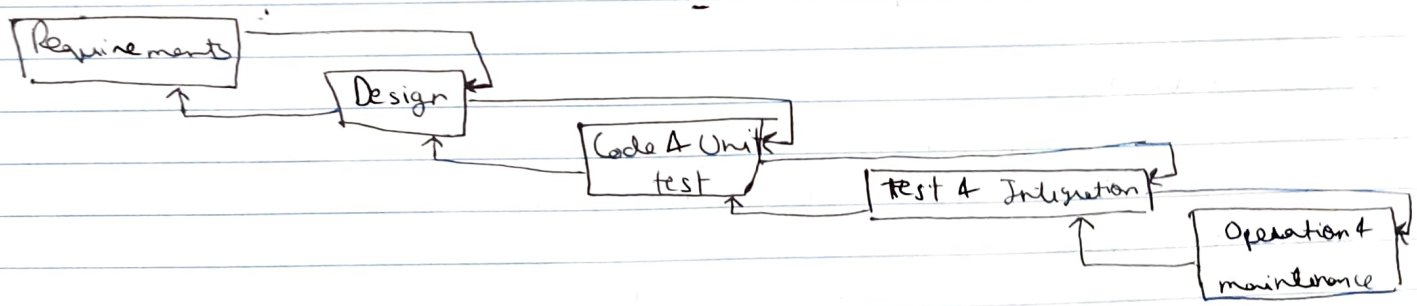
Easy to understand & implement
well-defined stages with clear milestones
proper documentation at every stage
suitable for small & well-defined projects

Disadvantages:

very difficult to accomodate changes once a phase is completed
testing is done late in the process
not suitable for complex or long term projects
no working software until late stage

- Evolutionary model

In this model, software is developed in multiple versions. The initial version provides basic functional and subsequent versions are enhanced based on basic user feedback until the final system is delivered



Disadvantages

limited control over reused components

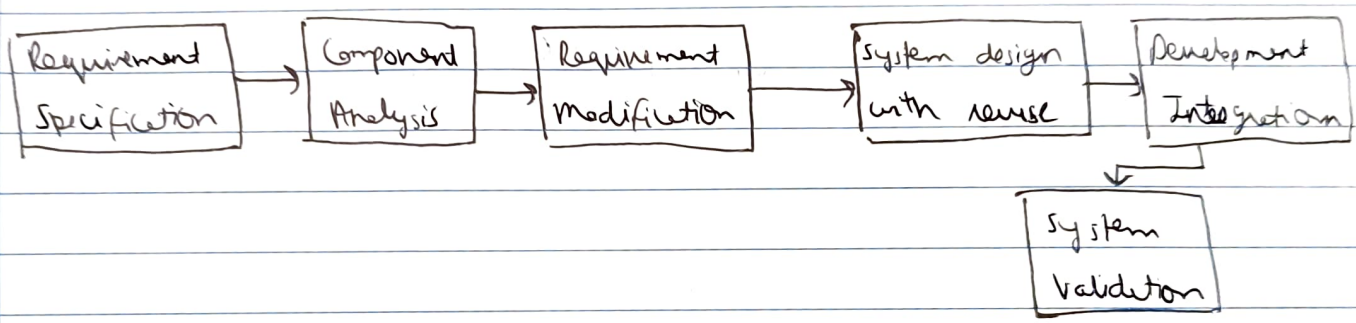
compatibility & integration issues

performance may be affected

suitable components may not always be available

- Incremental model

In the incremental model, software is developed & delivered in small increments. Each increment adds new functionality and final system is achieved after all increment are completed



Advantages

early delivery of partial working software

easier testing & debugging

flexible to requirement changes

reduced risk compared to waterfall

Disadvantages

requires good planning & design

total cost may increase

integration of increments can be complex

not suitable for very small projects
